Published <i>Without international search report and to be republished upon receipt of that report.</i>
(54) Title: HIV CHEMOKINES (57) Abstract Disclosed is a novel gene comprising an open reading frame encoded on the plus strand of the pro-viral DNA, and located in the region of HIV-1 long terminal repeat. The gene encodes a protein that is related to, and has a structural motif resembling that of chemokine proteins. Depending upon the ribosomal frameshift, a plurality of proteins may be translated from the antisense RNA. The protein has similarity with chemokine SDF-1 and may play a role as a cofactor with gp120 in the binding to and entry of HIV to a target cell.

HIV CHEMOKINES

This application claims the priority of provisional application serial no. 60/074,640 filed on 2/13/1998, and is also a continuation-in-part of copending application serial no. 08/698,652, filed on 8/16/1996.

5 This invention was made with government support under grant IR29AI38114-01 awarded by the National Institutes of Health. The government has certain rights in the invention.

10 BACKGROUND OF THE INVENTION

Field of the Invention

The present invention relates to a novel gene of HIV, the virus causing AIDS, which encodes a protein having an amino acid sequence that is closely related to
15 the chemokine family of proteins. More particularly, the invention relates to a novel HIV protein that may be a cofactor for binding to the chemokine receptor on human cells during the entry phase of infection.

20 Description of the Background and Related Art

1. The Chemokine Receptors as Coreceptor for HIV Infection

Efficient entry of HIV into target cells is dependent upon a high affinity binding of the viral
25 envelope glycoprotein, gp120, to the amino terminal domain of CD4, a protein expressed on the surface of the target cell. While CD4 is the primary virus receptor, CD4 alone is not sufficient for virus entry. Chemokine receptors have been identified as the coreceptors
30 involved in the entry of HIV into target cells.

Macrophage-tropic ("M-tropic") HIV-1 use the β -chemokine receptor CCR5, and less often receptor CCR3, as their coreceptor (Choe et al., 1996, *Cell* 85:1135-1148; Dragic et al., 1996, *Nature* 381:667-673; Deng et
35 al., 1996, *Nature* 381:661-666). Mutations in CCR5 appears to confer resistance to infection by M-tropic

- 2 -

HIV-1 viruses *in vivo* and *in vitro* (Samson et al., 1996, *Nature* 382:722-725). T-tropic (lymphotropic strains which grow in cells including transformed T cell lines) HIV generally use the α -chemokine receptor CXCR4 (also known as fusin, SDF-1 chemokine receptor, LESTR; Feng et al., 1996, *Science* 272:872-877). CXCR4 also can function as the primary receptor for HIV-2 entry and infection of human CD4-negative cells (Endres et al., 1996, *Cell* 87:745-756). Dual-tropic primary HIV-1 isolates, that can infect both macrophages and T cells, can use either CCR5 or CXCR4 (and possibly CCR3 or CCR-2b) as the coreceptor involved in virus entry (Doranz et al., 1996, *Cell* 85:1149-1158). There is evidence suggesting that the structure of the gp120 V3 loop influences the ability of HIV to bind the chemokine receptors on the target cell (Choe et al., 1996, *supra*; Doranz et al., 1996, *supra*).

2. HIV Secondary Structures

Single stranded RNA form localized regions of secondary structures such as hairpin loops and pseudoknot structures (Schimm, 1989, *Cell*, 58-9-12). A RNA population was isolated that bound to HIV reverse transcriptase and that has a pseudoknot consensus (Tuerk et al., 1992, *Proc. Natl. Acad. Sci., USA*. 59:6988-6992). Pseudoknots are structures in which there is an intramolecular base pairing of the "loop" sequence of an RNA hairpin to sequences either 5' or 3' to that hairpin. Pseudoknots are generally formed in nucleic acid sequences of about 30 to 60 nucleotides. Such intramolecular base pairing is key to the translation of RNA since the presence of pseudoknots can lead to frameshifting either in the 5' or the 3' direction (generally designated as -1 or +1) or for allowing read-

- 3 -

through. Translational frameshifting allows the expression of alternative translational products in a predictable stoichiometry (ala retroviral or HIV gag-pol fusion peptide); to allow the expression of alternative enzymatic activities; or as a mechanisms for autogenous control (see Farabaugh, 1996, *Microbiol Rev.* 104).

3. Chemokines

Chemokines are a superfamily of soluble proteins that are involved in immune regulation and in inflammatory processes (such as leukocyte recruitment). Generally, chemokines range in size from about 70 to about 100 amino acids, and in molecular size from about 8 kilodaltons (kD) to about 11 kD. Chemokine like proteins have also been described that are membrane bound (Pan et al., 1997, *Nature*, 387:611). The chemokines share related primary structure, particularly with a conserved motif of four cysteine residues. Early classification of chemokines was based on whether the first two cysteines are adjacent to each other ("CC chemokines"), or are separated by one amino acid ("CXC chemokines"). More recently, chemokines with a single "C" motif (for example lymphotactin) and "CXXXC" motif (for example, neutotactin) have been described. The α -chemokine receptor CXCR4 has been identified as a coreceptor required for HIV entry. The only known natural ligand for CXCR4 has been identified as the CXC chemokine SDF-1. SDF-1 has been shown to inhibit infection of CXCR4 and CD4 expressing cells by T-tropic HIV-1 strains (Oberlin et al., 1996, *Nature* 382:833-835). Thus, modified versions of chemokines are being tested to determine whether they may be used to block chemokine receptors from binding by HIV.

Kaposi's sarcoma is an AIDS-related malignancy. The Kaposi's sarcoma-associated herpesvirus (KHSV, human

- 4 -

herpesvirus 8) has been shown to encode a chemokine receptor ("GPCR") that is analogous in sequence and chemokine specificity to CXCR2 (Arvantikas et al., 1997, *Nature* 385:347-349). This is not the only instance in which a virus has apparently pirated a cellular gene encoding either a chemokine or a chemokine receptor. KSHV and Molluscum contagiosum have open reading frames that encode CC chemokines; and Herpesvirus Saimiri, human cytomegalovirus, KSHV, Equine herpesvirus-2, Swine pox virus, and capripox virus have open reading frames encoding chemokine receptors (Murphy, 1997, *Nature* 385:296-299; Neote et al., 1993, *Cell* 72:415-425).

4. HIV Proteins

The HIV genome is known to contain 8 open reading frames on the minus strand of the double-stranded DNA intermediate. From the HIV double-stranded intermediate, and from the HIV promoter located in the 5' LTR, mRNAs of plus strand polarity are transcribed from the minus strand DNA template (see Definitions section herein). Depending on the processing of the transcript, the mRNA may then be translated into one or more viral proteins including Gag, Pol, Vif, Tat, Vpu, Vpr, Rev, Env, and Nef. Additionally, ribosomal frameshifting is employed to enable gag pol protein. Effective transcription from the 5'LTR HIV promoter is dependent on the presence of Tat for transcriptional activation that dramatically increases the levels of viral mRNAs. A possibility was raised that the plus strand of the viral DNA contains a long open reading frame (ORF), located in the region of the genome complementary to the env gene sequence, that may encode a viral protein of 190 amino acids and a molecular mass of 20 kilodaltons (Miller, 1988, *Science* 239:1420-1422).

However, it is not apparent whether this possibility was confirmed, such as by the demonstration of the putative protein or its respective mRNA. In fact, it is noted in the publication that it is possible that the
5 ORF does not represent a true gene sequence. The possibility that bidirectional transcription occurs in HIV was further evaluated by Michael et al. (1994, *J. Virol.* 979-87).

Accordingly, there has been and continues to be a
10 long-felt need for the identification of novel HIV proteins which play a role in AIDS pathogenesis, and thus may be important targets of therapeutic intervention.

15 SUMMARY OF THE INVENTION

The present invention relates to the discovery of a novel gene comprising a open reading frame (ORF) in the plus strand of the viral DNA, and located in the HIV LTR. An antisense initiator element initiates
20 production by RNA polymerase of RNA transcripts of negative strand polarity (antisense RNA) utilizing the plus strand DNA as a template. Thus, using this mechanism, the novel HIV gene is transcribed by the cellular transcriptional apparatus. The gene encodes a
25 protein that is related to, and has a structural motif resembling that of a chemokine. More particularly, the protein has similarity to the chemokine family of proteins. These objects and further features and advantages of the invention will be better understood
30 from the description of the preferred embodiments when considered in relation to the figures.

BRIEF DESCRIPTION OF THE FIGURES

Figure 1a is a schematic representation of the HIV
35 genome illustrating the position of the HIV chemokine-

like gene in relation to other HIV genes and regulatory sequences (Meyers et al., 1995, *A compilation and analysis of nucleic acid and amino acid sequences*, Los Alamos National Laboratory, Los Alamos, New Mexico).

5 Figure 1b is a schematic representation of the LTR region of HIV illustrating the position of antisense RNA initiation.

 Figures 2a and 2b are schematic illustrations of the 5' LTR of HIV and the templates derived therefrom
10 for *in vitro* transcriptions.

 Figure 3a and 3b are representations of the results of *in vitro* transcription reactions using a eukaryotic transcription system and the templates illustrated in Figures 2a and 2b.

15 Figure 4 is a representation of the results of *in vivo* transcription reactions followed by analysis of RNA using reverse transcription and polymerase chain reaction in Jurkat T cells transfected with the HIV LTR Cat vector or control transfections.

20 Figures 5a and 5b are representations of the isolation of RNA transcripts originating off of the antisense initiator in stably transfected cells.

 Figure 6 is a schematic representation of the HIV-1 LTR showing various regulatory elements and
25 bidirectional transcription initiation sites, as well as primers utilized in RNA analysis by RT-PCR.

 Figure 7 is a schematic representation illustrating sequence analysis and alignment between amino acids of an HIV chemokine and other chemokines.

30 Figure 8 is a schematic representation illustrating sequence alignment between amino acids of HIV chemokines from various cell lines and patient HIV isolates.

 Figure 9 is a schematic representation illustrating the sequence and presence of pseudoknots.

Figure 10A-E are photomicrographic representations of the effect of transfection of a HeLa cell line with constructs containing the HIV LTR region.

5 DETAILED DESCRIPTION OF THE INVENTION

Definitions

By the term "operably linked" is meant, for the purposes of the specification and claims to refer to the chemical fusion (enzymatic restriction with subsequent
10 ligation) or synthesis of heterologous DNA with a nucleotide sequence that encodes an HIV chemokine such that the resultant recombinant DNA molecule is formed in a proper orientation and reading frame for the nucleotide sequence to be transcribed into functional
15 RNA. In the construction of the recombinant DNA molecule, it is generally preferred to position a promoter at a distance upstream from the initial codon of the nucleotide sequence that is approximately the same as the distance in its natural setting (e.g., as in
20 the HIV genome). However, as known in the art, some variation in the distance can be accommodated without loss of promoter function. Likewise, it is generally preferred to position an enhancer element at a distance upstream from the promoter, or incorporated into the
25 promoter sequences as a promoter element, or located between the promoter and the DNA molecule to be expressed. However, as known in the art, some variation in the placement can be accommodated without loss of the enhancer element's function.

30 By the term "expression vector" is meant, for the purposes of the specification and claims to refer to a DNA molecule which is operably linked to a nucleotide sequence that encodes an HIV chemokine such that the production of the HIV chemokine is effected in a
35 suitable host. The vector may include, but is not

limited to, a plasmid, phage, viral vectors, viral-like vectors, or a potential genomic insert.

By the terms "variant of the nucleotide sequence" or "variant of the gene" or "variant sequence" are meant, for the purposes of the specification and claims to refer to a nucleotide sequence that shares substantial identity (an identity of greater than about 70%, not taking third base degeneracy into account) with the gene encoding HIV chemokine. Such a sequence comparison can be performed using existing software known to those skilled in the art. Variants can be natural variants or variants produced by synthetic or mutagenic means for modifying the disclosed nucleotide sequences. With respect to such variations, and as appreciated by those skilled in the art, because of third base degeneracy, almost every amino acid can be represented by more than one triplet codon in a coding nucleotide sequence. Thus, a variant sequence can be modified slightly in sequence (e.g., substitution of a nucleotide in a triplet codon), and yet still encode its respective gene product of the same amino acid sequence as encoded by the disclosed nucleotide sequences. Further, variant sequences may have minor base pair changes which may result in variation (conservative substitution) in the amino acid sequence encoded. Such conservative substitutions are not expected to substantially alter the biologic activity of the gene product. A conservative substitution or modification of one or more amino acids are such that the tertiary configuration of the protein is substantially unchanged. "Conservative substitutions" is defined by aforementioned function, and includes substitutions of amino acids having substantially the same charge, size, hydrophilicity, and/or aromaticity as the amino acid replaced. Such substitutions, known to those of ordinary skill in the art, include glycine-alanine-

valine; isoleucine-leucine; tryptophan-tyrosine;
aspartic acid-glutamic acid; arginine-lysine;
asparagine-glutamine; and serine-threonine. A variant
sequence may contain a modification, being defined
5 functionally as resulting in a deletion or addition or
substitution of one or more amino acids which does not
impart a substantial change in the HIV chemokine that it
encodes; i.e., if the encoded HIV chemokine
substantially retains the activity of being a cofactor
10 in binding to a chemokine receptor. Such an encoded HIV
chemokine may be referred to as a modified variant of
HIV chemokine. Methods for synthetically producing such
variant sequences are known to those skilled in the art
(see, e.g. U.S. Patent Nos. 5,403,737 and 5,275,945).

15 By the terms "consisting essentially of" or
"consisting" a nucleotide sequence are meant, for the
purposes of the specification and claims to refer to the
base pair changes (substitution) in the nucleotide
sequence such as a change in the third base of a triplet
20 codon (third base degeneracy) or a change resulting in
the encoding of a conservative substitution in the amino
acid sequence encoded.

Proteins and peptides are chemical compositions
made up of a sequence of amino acid units. By the term
25 "consisting essentially" or "comprising" is meant as a
term, with an accepted meaning in the chemical patent
practice and for the purposes of the specification and
claims, to refer to the inclusion of unspecified amino
acids (deletion/addition/substitution) which do not
30 materially affect the basic and novel characteristics of
the composition; i.e. conservative substitution or
modification of one or more amino acids in that sequence
such that the protein or peptide substantially retains
the biological activity of being a cofactor in binding
35 to a chemokine receptor ("substantially retains" is
defined as 50% or more of such biological activity as

exhibited by HIV chemokine from an HIV clinical isolate).

By the term "similarity" are meant, for the purposes of the specification and claims to refer to amino acids that are not identical, but similar (amino acids having substantially the same charge, size, hydrophilicity, and/or aromaticity) between two amino acid sequences as determined by sequence comparisons performed using algorithms known to those skilled in the art.

By the term "identity" are meant, for the purposes of the specification and claims to refer to amino acid positions that are identical between two amino acid sequences as determined by sequence comparisons performed using algorithms known to those skilled in the art.

By the term "individual" is meant, for the purposes of the specification and claims to refer to any mammal, especially humans.

By the term "regulatory element" is meant, for the purposes of the specification and claims to refer to an promoter element motif which functions to facilitate binding or recruitment of RNA polymerase or transcription factors in the initiation, activity, and efficiency, of transcription. Eukaryotic regulatory elements include, but are not limited to an antisense initiator, an ATF site, TATA box, a TATA-like box (e.g., TTAA, TTAAA, TAT, TAATA), a CAAT box, a CAAT-like box (e.g., CTAATC), upstream stimulatory factor (USF), upstream sequence element (USE), and binding sites for transcription factors (e.g., AP-2, SP1, CRE, PEA-3, NF-IL6, NF-K β etc.).

By the terms "HIV Chemokine-like Protein" or "HIV-chemokine" is meant, for the purposes of the specification and claims, to refer to a protein having

the following distinguishing and functional characteristics:

- (a) a protein encoded by an HIV antisense open reading frame which encodes domains having at least 10% homology to amino acid sequences of chemokines.
- (b) is expressed by strains of HIV in at least one phase of virus replication, and is encoded by an open reading frame in the plus strand of the viral dsDNA intermediate, and located in the LTR region.

The term, "Chemokines" includes, but is not limited to, CC chemokines, CXC chemokines, single C motif chemokines (e.g. lymphotactin), CXXXC chemokines (e.g. neurotactin). The chemokine may be membrane bound or secreted.

By the terms "isolated and purified" and "substantially free from other proteins" is meant, for the purposes of the specification and claims, to refer to an HIV chemokine protein preparation that appears to be at least approximately 80% pure, and may be up to approximately 99% pure, as, for example, determined by gel electrophoresis, or liquid chromatography.

By the term "target cell" is meant, for the purposes of the specification and claims, to refer to a human cell which is infectable by HIV including, but not limited to, CD4+ cells bearing chemokine receptors, and CD4-negative cells bearing chemokine receptors; and also refers to human or other mammalian cells bearing chemokine receptors which receptors can bind to soluble HIV chemokine.

The present invention is directed to a gene, represented by an open reading frame in the plus strand of the viral ds DNA intermediate of HIV, which encodes a protein designated "HIV chemokine". One reason that this gene and its gene products remained unknown until the present invention was the lack of discovery and

characterization of the antisense initiator element
which allows initiation by RNA polymerases of RNA
transcripts of negative strand polarity utilizing the
plus strand of the HIV dsDNA LTR pro-viral intermediate
5 as a template (U.S. Patent application serial no.
08/698,652).

It is now established that chemokine receptors act
as coreceptors, with CD4, necessary for HIV to enter a
target cell. Additionally, certain chemokine receptors
10 (e.g., CXCR4) may act as the primary viral receptor, in
the absence of CD4, necessary for HIV to enter a CD4-
negative target cell (Endres et al., 1996, *Cell* 87:745-
756). Thus, HIV cofactors that act on their own or in
conjunction with gp120 in the binding to the target
15 cell's chemokine receptor represent components critical
in HIV pathogenesis. Chemokines, including RANTES, MIP-
1 α , and MIP-1 β , have been shown to bind to the CCR5
chemokine receptor and inhibit infection by HIV. SDF-1
has been shown to bind CXCR4 and inhibit infection by T-
20 tropic HIV-1 strains. Other chemokines, that bind to
one or more chemokine receptors that act as either
coreceptors or primary viral receptors, are being sought
as drug candidates in their natural state.
Additionally, such chemokines are being modified to
25 produce versions which may bind to the chemokine
receptor, but not act as an agonist (*Science* 275:1261-
1264, 1997; Simmons et al., 1997 *Science* 276:276-279).

The unexpected finding that HIV encodes its own
chemokine-like protein, and that the chemokine-like
30 protein may act as a cofactor with gp120 in the binding
to and entry of HIV to a target cell, is an important
consideration for therapeutic intervention. Thus, the
peptides derived from the HIV chemokine gene or variants
or modified versions of the HIV chemokine may be used to
35 block entry of target cells during various phases of HIV

infection and AIDS. Additionally, chemokine receptors may provide a method by which the HIV chemokine may be isolated and purified from HIV. Alternatively, one or more monoclonal or polyclonal antibodies having binding
5 affinity and specificity for the HIV chemokine may be used as affinity molecules immobilized to an affinity matrix for isolation and purification of the HIV chemokine.

Further, the unexpected finding that HIV encodes
10 its own chemokine-like protein provides evidence that the HIV chemokine is involved in at least one of the mechanisms of AIDS pathogenesis. In that regard, there may be biological properties of the HIV chemokine in addition to that of acting as a cofactor with gp120 or
15 an independent ligand for binding to a target cell, in the binding of HIV to and entry of HIV into a target cell. For example, chemokines in general, and more specifically β -chemokines such as MIP-1 α and MIP-1 β , can be potent chemoattractants for both monocytes and
20 specific subpopulations of lymphocytes (Schmidtayerova et al., 1996, *Proc. Natl. Acad. Sci. USA* 93:700-704). Thus, both human β -chemokine expression induced in HIV infection, and the HIV chemokine-like protein, may function to recruit uninfected T cells and monocytes to
25 sites of active viral replication or inflammation.

Such recruitment of uninfected T cells which are CD4+ to sites of active viral replication, such as in the lymph node, may play a role in the decline of CD4+ T cells observed in the progression of AIDS. Such
30 recruitment of mononuclear phagocytes to sites of active viral replication, such as in the brain, with subsequent activation of the mononuclear phagocytes to produce cytokines and NO (nitric oxide), may play a role in tissue pathology such as the neuropathogenesis observed
35 in AIDS (Shapshak et al., 1995, *Adv. Exp. Med. Biol.*

373:225-238; Bukrinsky et al., 1995, *J. Exp. Med.*

181:735-745; Achim and Wiley, 1996, *Curr. Opin. Neurol.*

9:221-225). Additionally, through genetic variation,

HIV may be able to control HIV chemokine expression

5 depending on the tissue type in which it is adapting.

In that regard, it is noted that HIV present in spinal cord and dorsal root ganglion harbour an LTR population

genetically distinct in sequence from that present in

other organs including lymph node, spleen, lung, and

10 peripheral blood (Ait-Khaled et al., 1995, *AIDS* 9:675-

683). Such variation in the LTR sequence can include

variations in the sequence of the HIV antisense

initiator element, and thus the expression of the HIV

chemokine from the antisense initiator element. The

15 heterogeneity of the HIV LTR isolated in various tissues

may reflect the predominant collection of mutations in

the cells infected in those tissues. Thus, an important

consideration in treating or preventing AIDS

pathogenesis in certain tissues may be to inhibit the

20 HIV chemokine from recruiting lymphocytes and

mononuclear phagocytes to sites of active viral

replication. Alternatively, the heterogeneity of the

HIV LTR may be part of the mechanism whereby the HIV

chemokine acquires the capacity to ligand with a

25 chemokine receptor expressed in a specific tissue as

illustrated in Figure 8 (+/- ribosomal frameshifting).

It should be noted that a CNS derived HIV chemokine

contains "CC" motif, whereas a LN/spleen contains "XC"

chemokine.

30 Kaposi's sarcoma is a malignancy that is rare in

individuals uninfected with HIV, but frequent in (up to

20 percent of) homosexuals with AIDS. Kaposi's sarcoma-

associated herpesvirus (KSHV) is thought to be the virus

that is the etiologic cofactor of Kaposi's sarcoma in

35 AIDS patients (Kedes et al., 1996, *Nat. Med.* 2:918-924;

Arvanitakis et al., 1997, *Nature* 385:347-349).

Recently, discovered was a chemokine receptor produced by KSHV ("KSHV GPCR") which may act as a cofactor in AIDS-related malignancies including Kaposi's sarcoma and primary effusion lymphoma (PEL) (Arvanitakis et al., 5 1997, *supra*). However, the expression of this chemokine receptor on an KSHV-infected cell is not sufficient to lead to altered growth or neoplastic transformation. Rather, signaling of cell-KSHV GPCR is required by a 10 cofactor produced during AIDS pathogenesis before altered growth or neoplastic transformation is initiated. Epidemiologic data supports this scenario, since KSHV appears to be sexually transmitted but malignancy primarily occurs only in AIDS patients; i.e., 15 a sexually transmitted agent leading to AIDS-related malignancy rather than just a sexually transmitted agent leading to malignancy. While chemokines of the CXC class or CC class have been shown to bind to KSHV GPCR (Arvanitakis et al., 1997, *supra*), a logical cofactor 20 that is HIV-related and thus explains the association between AIDS and malignancies including Kaposi's sarcoma and PEL is the HIV chemokine. That is, the HIV chemokine and KSHV GPCR are cofactors that interact to initiate cell signals leading to altered growth or 25 neoplastic transformation in KSHV-infected cells. To interact with the KSHV GPCR which is membrane bound in the KSHV-infected cells, the HIV chemokine may either be soluble (e.g., secreted from HIV-infected cells), or a component of a viral particle or HIV infected cell 30 membrane (e.g., interacting by itself as a membrane bound receptor or in conjunction with gp120).

Alternatively, the HIV chemokine and variants expressed in various tissues or cell lines may represent an ideal vaccine candidate for AIDS prevention in as 35 much as the isolated and purified HIV chemokine (and

variants) could be administered as vaccines to stimulate the human individual's intrinsic immune response to a "foreign" HIV chemokine without presumably interfering with human intrinsic chemokines necessary for
5 recruitment of inflammatory responses.

Because the HIV chemokine appears to play an important role for AIDS pathogenesis *in vivo*, one therapeutic approach is to consider using the HIV chemokine as an immunogen in a vaccine (including
10 multivalent) formulation against disease caused by HIV infection. Thus, isolated and purified HIV chemokine, or peptides made by enzymatically cleaving HIV chemokine or synthesis using the amino acid sequence of HIV chemokine as a reference, may be used as immunogens in
15 various vaccine formulations to prevent HIV entry into target cells, and/or in the prevention of tissue pathology in certain tissues caused by the HIV chemokine's recruitment of lymphocytes and mononuclear phagocytes to sites of active viral replication, and/or
20 to prevent HIV chemokine from interacting with potential chemokine receptors such as KSHV-GPCR.

More specifically, the resultant anti-HIV chemokine-antibodies may function to clear the tissue of chemoattractant HIV chemokine, and/or as "neutralizing"
25 antibodies to block HIV chemokine from acting as a cofactor in binding to chemokine receptors such as for the entry of HIV into target cells or such as expressed by a KSHV-infected cell. Additionally, according to the present invention, the HIV chemokine, or peptides
30 derived therefrom, may be used to generate HIV chemokine-specific antisera (human polyclonal antibody, or human-compatible monoclonal antibody including chimeric antibody) useful for passive immunization in HIV-infected individuals to clear the tissue of
35 chemoattractant HIV chemokine, and/or as "neutralizing" antibodies to block HIV chemokine from acting as a

cofactor in binding to chemokine receptors such as for the entry of HIV into target cells or such as expressed by a KSHV-infected cell.

Alternatively, peptides, modified peptides
5 (collectively referred to as "peptides") or modified variants of HIV chemokine derived from the amino acid sequence of the HIV chemokine may be used as a therapeutic agent. For example, such a peptide (e.g., 7 to 20 amino acids) or modified variant of HIV chemokine
10 may be synthesized so as to minimize inducing an immune response, or have reduced or lack function as a chemoattractant, but retain the receptor binding function of either an antagonist or an agonist. As an antagonist, the peptide or modified variant of HIV
15 chemokine would bind to at least one type of chemokine receptor which acts as a coreceptor or primary viral receptor for HIV entry or associated with AIDS pathogenesis, thereby blocking subsequent interaction of HIV with a target cell uninfected by HIV. In a
20 preferred embodiment, the antagonist would be able to bind to and block more than one type of such chemokine receptor (e.g., more than one of CCR5, CXCR4, CCR3, CCR-2b, KSHV GPCR, or any combination thereof). As an agonist, the peptide or modified variant of HIV
25 chemokine would bind to at least one type of chemokine receptor which acts as a coreceptor or primary viral receptor for HIV entry or associated with AIDS pathogenesis, thereby blocking subsequent interaction of HIV with a target cell uninfected by HIV. Additionally,
30 the binding of the agonist to the target cell chemokine receptor would trigger the receptor to signal the cell to downregulate the expression of the chemokine receptor, the same signal generated by binding of a chemokine to its receptor (see, e.g., chemokine agonist
35 in receptor binding- Hunter et al., 1995, *Blood* 86:4400-4408). In a preferred embodiment, the agonist would be

able to bind to and block more than one type of such chemokine receptor (e.g., more than one of CCR5, CXCR4, CCR3 or CCR-2b, or any combination thereof). In using such a peptide or modified variant of HIV chemokine, it is noted that human testing of a MIP-1 α variant (BB-10010) in cancer and HIV studies seems to be well tolerated and not inflammatory (Lord et al., 1996, *Br. J. Cancer* 74:1017-1022).

As reviewed above, HIV chemokine production may be modulated, depending upon the tissue type to which it has adapted. Thus, isolated and purified HIV chemokine, or peptides derived therefrom, may be used as an antigen in diagnostic immunoassays directed to detection of HIV infection for staging or to monitor response to anti-viral therapy by measuring the body fluid (e.g., serum, cerebral spinal fluid (CSF), or urine) titer of any anti-HIV chemokine antibody that may be present in the HIV-infected individual. Also, isolated and purified HIV chemokine, or peptides derived therefrom, may be used to generate HIV chemokine-specific antibody which may be useful as reagents for diagnostic assays directed to detecting the presence of HIV chemokine in clinical specimens. Measurements of chemokine levels for chemokines that are cell differentiation-associated (Vinante et al., 1996, *Haematologica* 81:195-200), or for monitoring efficacy of therapy (Segawa et al., 1996, *Intern. Med.* 35:155-158) have been described previously. Alternatively, reverse transcription-nucleic acid amplification reactions with primers specific for amplifying all or a portion of the HIV chemokine sequence may be utilized to detect the presence of the HIV chemokine sequences in clinical specimens for staging or to monitor response to anti-viral therapy. Similar methods of nucleic acid amplification have been described previously for determining cell type-specific

heterogeneity of the HIV-1 V3 loop in HIV-infected individuals (Yamashita et al., 1994, *Virology* 204:170-179); or to monitor the LTR variation (Ait-Khaled et al., 1995, *supra*).

- 5 For purposes of the description, the methods and compounds of the present invention will be illustrated in the following examples.

EXAMPLE 1

- 10 A gene encoding an HIV chemokine according to the present invention can be obtained by isolating the HIV dsDNA intermediate from an HIV-infected cell, or may be synthesized in vitro by reverse transcriptase-nucleic acid amplification from the antisense mRNA originating
15 from the HIV antisense initiator, HIVaINR. Figure 1 illustrates the position of the HIV chemokine gene in relation to other HIV genes and regulatory elements.

- Alternatively, since the HIV chemokine gene is coded for by the plus strand of the HIV, which is
20 complimentary to the minus strand, the sequence of a given strain of HIV chemokine gene can be deduced from the known LTR region sequences of HIV strains available in gene databanks (see also Human retroviruses and AIDS 1995, a compilation and analysis of nucleic acid and
25 amino acid sequences. Ed. G. Mayers., Los Alamos national Laboratory). To further illustrate this embodiment, the nucleotide sequence of the antisense gene encoding the HIV chemokine of 1bl revINRold was deduced (SEQ ID NO:1) utilizing the nucleotide sequence
30 of the HIV minus strand. This sequence termed as "HIV chemokine gene" has an antisense initiator, aINR, at position 60-68 (SEQ ID NO:1). The aINR has the consensus 5' Py Py A N T/A Py Py 3' as disclosed in our copending application serial no. 08/698,652. A TATA box
35 is present about 42 nucleotides downstream from the site

of antisense initiation and in the opposite orientation at nucleotides 110-114. There is also an ATF consensus site upstream of the antisense gene. The open reading frame encodes a protein of 81 amino acids (SEQ ID NO:2).

5 The production of this protein requires a frameshift at the nucleotide at position 263 of SEQ ID NO:1. The frameshifting is potentiated by the formation of pseudoknot structures in the RNA. The 1bl revINRold sequence is derived from pNLgag (Adachi et al., J.

10 *Virology*, 59:284-291) which has a mutation following the first start codon of HIV chemokine at nucleotide 114 such that a stop codon immediately follows. Therefore, the second start site at nucleotide 206 is utilized. However, most other HIV strains actually have the first

15 start codon available and potentially viable, which would entail sets of ribosomal frameshifts and code for larger proteins.

In another illustration of this embodiment the nucleotide sequence of the antisense RNA encoding HIV

20 chemokine of SF-2 strain of HIV was deduced (SEQ ID NO:6) from the known nucleotide sequence of the minus strand. The first start codon is at nucleotide 52. The second start codon is at nucleotide 144. The larger protein (SEQ ID NO:7), starting at the first start codon

25 has 112 amino acids and requires a (+1) frameshift at nucleotide 133 and -1 ribosomal frameshift at nucleotide 265. Another large protein (SEQ ID NO:14) is obtained by a (-1) frameshifting at nucleotide 133 and a (+1) frameshifting at nucleotide 265. If the sequence is

30 read through, a protein of SEQ ID NO:15 is possible. Two shorter proteins are also possible starting at the second start codon. The first of these two (SEQ ID NO:8) has 82 amino acids and requires two (-1) ribosomal frameshifts at nucleotide 200 and nucleotide 265. The

35 second of the shorter proteins (SEQ ID NO:9) has 81 amino acids and requires a ribosomal frameshift at

nucleotide 201. It should be noted that both a 5' terminal hairpin, as well as pseudoknot motifs are present within the HIVaINR-generated antisense RNA (Figure 9). These pseudoknots closely resemble
5 synthetic RNA pseudoknots selected for binding to HIV-reverse transcriptase (Tuerk et al., 1992, *Proc. Natl. Acad. Sci. USA*, 89;6988-6992). Similarly, sequences of antisense RNA of other strains of HIV can be deduced from the nucleotide sequence of the minus strand. These
10 sequences are found to display at least 80% homology to the sequence of SEQ ID NO:6.

To further illustrate this embodiment, the nucleotide sequence of the antisense RNA encoding HIV chemokine of a HIV strain isolated from the CNS of a
15 patient was deduced from the known nucleotide sequence of the minus strand (SEQ ID NO:25). The first start codon is at nucleotide 52. Depending upon the frameshifting or readthrough, multiple proteins are possible. For a (+1) frameshift at 133 nucleotide and
20 (-1) frameshift at nucleotide at 265, a protein of SEQ ID NO: 10 is obtained. For a ribosomal frameshift of (-1) at nucleotide at 133, and a (+1) frameshift at nucleotide, a protein of SEQ ID NO:11 is obtained. If the frameshifts are read through, a protein of SEQ ID
25 NO:15 is obtained.

In another illustration, the nucleotide sequence of the antisense RNA encoding HIV chemokine of a HIV strain isolated from the lymph node and spleen of a patient was deduced from the known nucleotide sequence of the minus
30 strand (SEQ ID NO:26). The first start codon is at nucleotide 52. Depending upon the frameshifting or readthrough, multiple proteins are possible. For a (+1) frameshift at 133 nucleotide and (-1) frameshift at nucleotide at 280, a protein of SEQ ID NO: 12 is
35 obtained. Additional amino acids are coded for in some variants. For a ribosomal frameshift of (-1) at

- 22 -

nucleotide at 133, and a (+1) frameshift at nucleotide 280, a protein of SEQ ID NO:13 is obtained. If the frameshifts are read through, a protein of SEQ ID NO:16 is obtained.

5 Similarly, amino acid sequences for chemokine-like proteins from other strains of HIV can be obtained from the antisense RNA sequence. Thus, the amino acid sequence for (+1), (-1) frameshift for YU2 strain is disclosed in SEQ ID NO:16 and SEQ ID NO:17, while the
10 amino acid sequence obtained by readthrough is SEQ ID NO:18.

 The amino acid sequence of a chemokine-like protein for ELI strain with read through is disclosed in SEQ ID NO:19.

15 The amino acid sequence of a chemokine from another strain, p896, with several readthrough events is disclosed in SEQ ID NO:20.

 It should also be noted that constructs which contain HIV LTR regions may also be used to produce HIV
20 chemokines-like proteins. For example, the antisense RNA sequence of pHIV-CAT which is commonly used to transfect cells and was used to transfect cells as disclosed herein was obtained by standard sequencing techniques and is disclosed in SEQ ID NO:21. This
25 antisense RNA encodes a protein SEQ ID NO:22.

 From these illustrations it will be evident to those skilled in the art that the sequence of the antisense RNA encoding chemokine-like proteins from HIV strains or double stranded constructs derived from the
30 HIV strains, can be deduced. It will also be appreciated by those skilled in the art that the plasticity of the HIV genome leads to variations in the antisense RNA sequence. Such variations are intended to be included within the scope of this disclosure.
35 Ribosomal frameshifting adds another element of

plasticity to the sequence of encoded protein and is also intended to be within the scope of this disclosure.

In another illustration of this embodiment, the HIV chemokine gene including the open reading frame and HIV chemokine encoding sequence from different strains of HIV can be isolated. HIV dsDNA intermediate from an HIV-infected cell can be isolated or RNA transcripts may be amplified *in vitro* by reverse transcription from the HIV RNA by using oligonucleotide primers which specifically hybridize to the nucleotide sequence of SEQ ID NO:1. Using this sequence, it will be appreciated that one skilled in the art may design oligonucleotide primers useful in the nucleic amplification of the HIV chemokine gene, or oligonucleotide probes useful for detection of amplified sequences containing all or a portion of the HIV chemokine-like protein encoding sequence in other strains of HIV isolated from different individuals or of HIV isolated from different tissues of the same individual.

A further alternative is to isolate either HIV RNA or HIV dsDNA from HIV-infected cells using methods known to those skilled in the art, and then use techniques that would result in the amplification and/or cloning of an HIV chemokine coding sequence. Following determination of the nucleotide sequence of the isolated HIV chemokine, further characterization may be performed by computer analysis using software known in the art to record the DNA sequence and determine the correct reading frame, codon usage, predicted amino acid sequence and molecular size of the encoded HIV chemokine, and comparison of the amino acid sequence of that particular HIV chemokine with the amino acid sequence of other HIV chemokines.

- 24 -

EXAMPLE 2

This embodiment illustrates the generation of HIV chemokine RNA transcripts off of the antisense initiator, HIVaINR. Since HIV-1, once integrated into a human host cell chromosomal DNA, is dependent upon eukaryotic transcription factors and RNA polymerases to transcribe its genes (Cullen, 1992, *Microbiol. Reviews*, 375-394), a eukaryotic transcription system (commercial *Drosophila* embryo nuclear extract transcription system) that can efficiently transcribe from eukaryotic initiators in vitro was used to investigate whether eukaryotic transcription could initiate from the HIVaINR. Four different HIV-1 LTR fragments, illustrated in Figure 2a, were generated by polymerase chain reaction using HIV-LTR templates and primers containing bacteriophage T7 or Sp6 polymerases, as previously described (Ludwig et al., 1995, *Nuc. Acid Res.* 23:3792-3793), which method is hereby incorporated by reference. The fragments are 5'Hae III PBS (Sp6) 3' which includes two Sp1 sites and TATA box and extends through the primer binding site (PBS; Fragment 1); 5' PvuII-PBS (Sp6) 3' fragment which lacks all of the Sp1 sites and bisects the TATA box (Fragment 2); 5' (T7) PvuII-SacI (Sp6) 3' fragment which truncates the TAR region 48 base pairs from the mRNA cap site and start site (Fragment 3); and 5' (T7) R-BssHII (Sp6) 3' fragment which contains no HIV-1 promoter Sp1 sites or TATA box but contains the TAR region DNA (Fragment 4).

In vitro transcription reactions were performed with each template using a eukaryotic transcription system (*Drosophila* Nuclear Extract, Promega) according to manufacturer's instructions, to initiate transcription off of HIVaINR. This eukaryotic transcription system used *Drosophila* nuclear extracts to supply transcription factors and the eukaryotic RNA

polymerases. Each of the *in vitro* transcription reactions was then treated with DNase I to remove DNA template, followed by phenol chloroform extraction and by ethanol precipitation to remove the DNase from the synthesized RNA. The RNA transcripts were hybridized
5 either to a biotin-labeled sense RNA probe (5' (T7) R-U5-PBS-BssH II (SP6) 3') Figure 3a, lane 1-6 or to biotinylated antisense RNA probe (5' (SP6) BssH II-PBS-U5-R (T7) 3') Figure 3a, lanes 10-15. The hybridized
10 RNA was subjected to ribonuclease T1 digestion and analysis by electrophoresis on a denaturing 8% polyacrylamide gel electrophoresis (PAGE). The size of RNA transcript was observed to be 25 nucleotides distinct from the protected TAR loop or undigested probe
15 (Figure 3a, lanes 2-6; which was absent in control lane 1).

As shown in lanes 10-15, Figure 3a, no expected size transcripts were initiated in the usual sense orientation, as demonstrated by the failure of the
20 antisense probe to hybridize, and thereby protect, sense transcripts in a RNA digestion assay. It is important to note that for the *in vitro* transcription experiments, *Drosophila* nuclear extracts were used, which intrinsically lack Sp1 protein. Thus a major driving
25 force for sense transcription from the HIV-1 promoter *in vitro* was lacking, enabling the observance of antisense transcription in isolation. It was observed that primer extension utilizing HIV-specific biotinylated primers and unlabeled dNTPs allowed specific analysis of
30 the RNAs synthesized off the HIV LTR templates while eliminating the background contribution seen from the *Drosophila* nuclear extract (Figure 3b). Simultaneous *in vitro* transcription reactions performed using *Drosophila* nuclear extract and either the original HIV-1 LTR
35 (labeled O), or truncated portions of the HIV-1 LTR extending from the *Ava*I to the *Hind*III site. (labeled

- 26 -

A), or extending from the *Ava*II to the *Hind*III site (labeled B), as diagrammed in Figure 2b) allowed delineation of the 3' end of the antisense transcript between the *Ava*II site and the U3 end of the HIV-1 LTR (Figure 3b). Control transcription reactions receiving no template were labeled NT. Primer extension with sense *Ava*I or *Ava* II primers, with RNA synthesized from the truncated A or B templates demonstrated cDNA of the expected size for an antisense transcript generated off the HIV aINR.

EXAMPLE 3

This embodiment is directed towards demonstration of *in vivo* transcription from HIV-aINR. An *in vivo* eukaryotic transcription system may be used to produce mRNA transcripts from human cell lines (e.g., a lymphoid cell line such as Jurkat T cells, or a mononuclear phagocyte cell line) which have been transfected with a eukaryotic vector containing the coding sequence for HIV chemokine operably linked to the HIV antisense initiator or other functional eukaryotic promoter including one or more regulatory elements.

To further illustrate this embodiment, *in vivo* transcription from the HIV-aINR was analyzed by reverse transcription-polymerase chain reaction of RNA isolated from human Jurkat T cells which has been transfected with pHIV-CAT. Plasmid pHIV-CAT contains the HIV-1 LTR U3 and R sequences 5' to the chloramphenicol acetyltransferase (CAT) gene. Transfections of plasmid DNA were performed in the presence of a transfection agent (Transfectam™, Promega). Briefly, plasmid DNA (0.086 µg plasmid DNA per 0.182 µl transfectum per well for 2 hours) was incubated with the cells using conditions as essentially described by the manufacturer. Control transfection reactions included pHIV-CAT plus

pSV- β gal plus transfection reagent (to assess transfection efficiency), transfection reagent alone ("mock" transfection), or no treatment at all. Cells were then resuspended in culture medium and continued in culture for two days. RNA was then extracted from the pelleted cells, and purified using standard techniques well known in the art. The purified RNA was then split and subjected to reverse transcription using a 5' *Ava*I sense primer (SEQ ID NO: 3), to anneal with and extend HIV-antisense transcripts, followed by amplification by PCR with 30 cycles of denaturing (94^o, 45 seconds), reannealing (70^oC, 45 seconds), and extension (72^oC, 2 minutes) using the *Ava*I sense primer and either a 3' antisense primer (SEQ ID NO:4), or a 3' *Mae*I antisense primer (SEQ ID NO:53). The reverse-transcription-PCR products were then analyzed by 3% agarose gel electrophoresis, transferred to a nitrocellulose membrane (Biodyne) and detected colorimetrically.

The results are illustrated in Figure 4. The lanes marked "M" represent DNA size standard markers. HIV-1 RNA transcripts could be detected only in RNA isolated from Jurkat T cells transfected with pHIV-CAT (Figures 4, 7a-12a), using a 5' sense primer (5' *Ava*I) to extend off the antisense transcript in the reverse transcription reaction, followed by PCR amplification with the 5'*Ava*I sense primer and a biotinylated antisense 3' 441 primer containing sequences complementary to beginning TAR sequences. As shown in Figure 4, lanes 1a-3a), no product was obtained in simultaneous identical reverse-transcription PCR reactions performed using total cellular RNA isolated from Jurkat T cells that were mock transfected, and received transfectam but no DNA template (NT). No products were obtained when the same samples as in lanes 7a-12a in Figure 4, were simultaneously analyzed by

reverse transcription PCR with 5' *Ava*I in the reverse transcription step, but amplified with an alternative 3' *Mae*I antisense primer during PCR (lanes 7b-12b). The 3' *Mae*I antisense primer is complementary to sequences in TAR region situated beyond the HIV aINR (Figure 6), and is therefore, not expected to generate amplified products from authentic antisense RNA. This control, therefore, serves to confirm the authenticity of transcripts originating from the HIVaINR.

10 In another illustration of this embodiment cells stably transfected with HIV were used to demonstrate the presence of transcripts originating from the HIVaINR. Therefore, cell line U38 containing stably transfected HIV-1 LTR-CAT gene sequences were analyzed for in vivo
15 antisense HIV-1 transcripts. The cells were cultured with or without stimulation with calcium ionophore and phorbol ester. Total RNA was extracted by standard methods, split equally three ways and treated either with a single DNase treatment, two DNase treatments, or
20 two DNase treatments plus RNase digestion. The samples were then subjected to reverse transcription-PCR. For reverse transcription PCR analysis, each treated sample was analyzed five ways: for the presence of antisense HIV-1 transcripts (Figures 5a and 5b, lanes 2-7); for the presence of sense HIV-1 transcripts (Figure 5a and 5b, lanes 28-33); for the presence of DNA contamination (Figure 5a and 5b, lanes 20-25); for G3PDH RNA (Figure 5b, lanes 37-42); and for reverse transcription PCR performed without the reverse transcriptase (Figure 5a and 5b, lanes 11-16. Internal controls, consisting of primer without template (Figure 5, "Pr", lanes 8,17,26,34 and 43) were also run to confirm that the reverse transcription-PCR reaction mixture were not contaminated with templates. A separate control set
35 with primers and an internal control standard RNA

template (Figure 5, "Is", lanes 1,10,19,27, and 36) was run to confirm comparable primer annealing efficiency. In addition, RT+/- and PCR (kit) +/- kit controls were run in lanes 44-47. Thus, Figure 5a illustrates the

5 biotin-labeled RT-PCR products following transfer to a membrane and colorimetric detection (G3PDH primers were not labeled), and 5b illustrates the RT-PCT products as photographed following ethidium bromide staining of the gel prior to transfer.

10 As shown in Figures 5a and 5b, antisense RNA transcripts are made off of the HIVaINR in stably transfected cells in vivo, at a level (lanes 2-7) comparable to intrinsic cellular G3PDH RNA transcripts (Figure 5b, lanes 37-42) and sense HIV-1 transcripts

15 (lanes 28-33). RNase digestion (lanes 4 and 7), but not DNase digestion (lanes 2,3,5 and 6) of the U38 total cellular RNA eliminated the antisense RNA product band(s) of reverse transcription-PCR reactions. The identical RNA samples that had RNase treatment also

20 demonstrated the elimination of products for G3PDH RNA (Figure 5b, lanes 39 and 42, and for sense HIV RNA lanes 30 and 33). Antisense RNA generated off the HIV-1 LTR and analyzed by reverse transcription using sense primer (5' *Ava*I) generated a cDNA when the sense 5' primer or

25 the antisense 3' 441 primers were present in the PCR reaction but not when an antisense *Mae*I primer was present in the PCR reaction. The *Mae*I primer anneals outside of the transcription start site for antisense RNA. Third, while DNA contamination can be observed

30 with U38 total cellular RNA samples obtained from cells stimulated with Ca ionophore and PMA, and treated with DNase only once (Figure 5a and 5b, lane 14), no contamination was observed with any of the total cellular RNA samples obtained from unstimulated U38

35 (Figure 5a and 5b, lanes 11-13, which correspond to the same RNA samples analyzed in lanes 2,-4).

In summary, this embodiment demonstrates the generation of authentic antisense transcripts in vitro and in vivo.

5

EXAMPLE 4

An HIV chemokine according to the present invention may be characterized by its amino acid sequence, which may vary depending on the HIV isolate of origin, including tissue site of the HIV isolate of origin. By
10 using nucleotide sequence data, the amino acid sequence of the HIV chemokine protein, as shown in SEQ ID NO:2 for 1b1 revINRold, SEQ ID NOs: 7,8 and 9 for SF-2 strain is derived.

In one illustration of this embodiment, using a
15 gene database, and a software alignment program known in the art, a sequence comparison was made between a HIV chemokine amino acid sequence and various mammalian chemokines. Figure 7 illustrates a comparison of the deduced amino acid sequence of HIV chemokine of the
20 present invention and other chemokines. After introducing gaps in the SDF-1 sequence, a consensus was obtained for 23 of the amino acids of HIV chemokine (1b1 revINRold; SEQ ID NO:2) and SDF-1; for 20 of the amino acids of HIV chemokine (1b1 revINRold; SEQ ID NO:2) and
25 IL8-human, and HIV chemokine and I-309 (Figure 7). The α -chemokine receptor CXCR4 has been identified as a coreceptor required for HIV entry, and one natural ligand for CXCR4 has been identified as CXC chemokine SDF-1. Thus, the relatedness of the HIV chemokine to
30 SDF-1, as shown in FIG. 7, implicates the HIV chemokine as being a factor (alone) or a cofactor (with gp120) in binding to chemokine receptors required for HIV entry into a target cell. That SDF-1 has been shown to inhibit infection of CXCR4 and CD4 expressing cells by
35 T-tropic HIV-1 strains (Oberlin et al., 1996, *supra*) suggests that isolated and purified HIV chemokine may

also inhibit infection of CXCR4 and CD4 expressing cells by HIV-1 strains. Based on these findings, the HIV chemokine may be used to generate peptides or a modified variant of the HIV chemokine for use as a vaccine; as an
5 antigen to generate antisera such as for neutralizing antibodies and for diagnostic immunoassays; as an agonist of HIV chemokine; as an antagonist to HIV chemokine and to generate primers or probes from the corresponding HIV chemokine coding sequence for
10 diagnostic and prognostic applications.

In another illustration of this embodiment, the amino acid sequences of HIV chemokines from different strains of HIVs was deduced from their known nucleotide sequences of the minus strand available from gene
15 databases. Using commercially available software, the amino acid sequence of HIV chemokines transcribable from the plus strand was compared for cell lines and HIV isolates from patients. The cell lines compared were TCLA, SF-2, macrophage trophic primary viral (YU2). The
20 data from HIV isolates of patients was obtained from either central nervous system ((Pt)CNS) or lymph node and spleen isolates ((Pt)LN/SP. As illustrated in Figure 8, the amino acid sequence of the HIV chemokines shows a high degree of homology with the N-terminus
25 being more conserved. Although the amino acids comprising this portion of the amino terminus of all HIV chemokines analyzed to date seem to be conserved, one skilled in the art will appreciate that minor variations in the amino acid sequence may occur, particularly since
30 HIV is known to frequently vary its sequences. However, the comparison suggest that the conservation of this region may reflect a common mechanism for structure (e.g., folding) or for regulation. The plasticity of the RNA (secondary tertiary structures i.e. pseudoknots)
35 enables more than one potential reading frame to be utilized.

EXAMPLE 5

The present invention relates to an HIV gene, isolated from a strain of HIV, wherein the gene encodes an HIV chemokine-like protein. With sequence
5 information, like that shown in SEQ ID NOs: 1 and 2, other polypeptides can be produced which display "HIV chemokine" activity. More particularly, variant nucleotide sequences can be natural variants or variants produced by synthetic or mutagenic means for modifying
10 the disclosed nucleotide sequences. Methods for synthetically producing such variant sequences are known to those skilled in the art of protein design. In designing such variants, one needs to consider avoiding mutations of sequences that encode the structurally and
15 functionally-involved amino acids, or the cysteine residues involved in disulfide bond formation, which may negatively affect the role of the HIV chemokine in binding to chemokine receptors. In that regard, it is noted that the receptor-binding pocket (also called the
20 "hydrophobic pocket") is a domain of the HIV chemokine involved in binding to chemokine receptors. The domain can be determined using methods known in the art in which chimeras of chemokines, in which domains are interchanged, are tested for their ability to bind to a
25 specific receptor (Heinrich and Bravo, 1995, *J. Biol. Chem.* 270:28014-7; Hammond et al., 1996, *J. Biol. Chem.* 271:8228-35). These standard techniques have been used to determine which binding domain(s) can function as an agonist, partial agonist, or an antagonist (Heinrich and
30 Bravo, 1995, *supra*). Thus, the potential domains of HIV chemokine, resembling that of other chemokines can be interchanged with similar domains of SDF-1 in forming chimeras whose binding specificity to CXCR4 (or CXCR4 and CD4) expressing cells can then be evaluated using
35 methods known in the art (Oberlin et al., 1996, *supra*,

Bleul et al., 1996, *supra*). Similarly, chimeras made of domains of HIV chemokine with another chemokine (e.g., RANTES or MIP-1 α , or MIP-1 β) and tested against β -chemokine receptor expressing cells (CCR-5, or CCR2b, or CCR3) may be used to determine the domain(s) of HIV chemokine that can function as an agonist, partial agonist, or an antagonist. Analysis of chimera binding to β -chemokine receptor expressing cells has been described previously (see, e.g., Rucker et al., 1996, Cell 87:437-446). Identifying the amino acids making up a HIV chemokine functional domain in binding specificity to a chemokine receptor enables the design of peptides or modified variant HIV chemokine which may be useful for therapeutic and/or diagnostic applications.

In one embodiment, the variant sequence may be produced by site-directed mutagenesis using one of the several methods for such mutagenesis which are known to those skilled in the art (see, e.g. U.S. Patent No. 5,397,705). For example, site directed mutagenesis using oligonucleotides comprises the steps of (i) synthesizing an oligonucleotide with a sequence nearly identical to a sequence in the HIV chemokine gene except that the oligonucleotide sequence contains the desired nucleotide substitution (encoding for a mutation in the amino acid sequence); (ii) hybridizing the oligonucleotide primer to a template comprising the nucleotide sequence encoding an HIV chemokine; and extending the oligonucleotide primer using a DNA polymerase. The resultant variant sequence may then be incorporated into an expression vector which is then used to genetically engineer a host cell to recombinantly produce a polypeptide having at least partial, if not full, HIV chemokine binding specificity.

In another embodiment, genetic engineering techniques can be used to generate nucleic acid molecules comprising a variant sequence that is a

substantial portion of the HIV chemokine gene. As apparent to one skilled in the art, from the HIV chemokine gene sequence, and from a restriction map thereof, it can be determined which restriction enzyme or combination of restriction enzymes may be used to generate nucleic acid molecules encoding a modified variant of HIV chemokine having some of, the same as, or more than, the binding specificity exhibited by the HIV chemokine of natural HIV isolates. Restriction enzyme selection may be done so as not to destroy the binding domain/hydrophobic pocket of the resultant polypeptide. Consequently, restriction enzyme combinations may be used to generate nucleic acid molecules (variant sequences), which when inserted into the appropriate vector, are capable of directing the production of a modified variant of HIV chemokine having some of, the same as, or more than, the binding specificity exhibited by the HIV chemokine of natural HIV isolates.

In a further embodiment, an HIV chemokine may be made into a modified variant of HIV chemokine by chemical means. For example, a modified variant (a "derivative") of the chemokine RANTES was created by chemical modification of the amino terminus (Simmons et al., 1997, *Science* 276:276-279). The amino terminus was modified by reacting it with aminooxypentane (AOP). The resultant AOP-RANTES was a potent antagonist which inhibited infection of target cells by M-tropic HIV-1 strains (indicating full receptor occupancy), yet did not induce chemotaxis. Thus, the amino terminus of HIV chemokine may be reacted with AOP by amino terminal oxidation using the methods described by Simmons et al. (*supra*) to achieve a modified variant of HIV chemokine that may act as an antagonist.

EXAMPLE 6

This embodiment illustrates that a nucleic acid molecule comprising a nucleotide sequence encoding an HIV chemokine, a variant sequence encoding a modified
5 variant HIV chemokine, or a nucleotide sequence encoding a peptide derived from HIV chemokine (collectively referred to as "nucleotide sequence"), can be inserted into a vector for expression in a host cell system. Successful expression of the HIV chemokine, modified
10 variant HIV chemokine, or peptide derived from HIV chemokine (collectively referred to as "recombinant HIV chemokine"), requires that either the insert comprising the nucleotide sequence encoding the recombinant HIV chemokine, or the vector itself, contain the necessary
15 elements for transcription and translation (regulatory elements) which is compatible with, and recognized by the particular host system used for expression. A variety of host systems may be utilized to express the recombinant HIV chemokine, which include, but are not
20 limited to bacteria transformed with a bacteriophage vector, plasmid vector, or cosmid DNA; yeast containing yeast vectors; fungi containing fungal vectors; insect cell lines infected with virus (e.g. baculovirus); and mammalian cell lines transfected with plasmid or viral
25 expression vectors, or infected with recombinant virus (e.g. vaccinia virus, adenovirus, adeno-associated virus, retrovirus, etc.).

Using methods known in the art of molecular biology, including methods described above, the
30 antisense initiator, aINR, or other promoters and regulatory elements can be incorporated into the vector or the nucleotide sequence encoding the recombinant HIV chemokine, to increase the expression of the recombinant HIV chemokine, provided that this increased expression
35 is compatible with (for example, non-toxic to) the particular host cell system used. The selection of the

promoter will depend on the expression system used.

Promoters vary in strength, i.e. ability to facilitate transcription. Generally, for the purpose of expressing a cloned gene, it is desirable to use a strong promoter in order to obtain a high level of transcription of the nucleotide sequence and expression into the recombinant HIV chemokine product. For example, bacterial, phage, or plasmid promoters known in the art from which a high level of transcription has been observed in a host cell system comprising *E. coli* include the lac promoter, trp promoter, tac promoter, recA promoter, ribosomal RNA promoter, the P_R and P_L promoters, lacUV5, ompF, bla, lpp, and the like, may be used to provide transcription of the inserted nucleotide sequence encoding the recombinant HIV chemokine. Promoters known in the art for transcription to occur in mammalian cells may include viral or viral-like basal promoters like the SV40 late promoter, the RSV promoter, the CMV immediate early promoter, adenovirus major late promoter, the MMTV promoter, and a VL30 promoter; and cellular promoters including metallothione promoters (See, e.g., Larsen et al., 1995, *Nucleic Acids Res.* 23:1223-1230; Donis et al., 1993, *BioTechniques* 15:786-787; Donda et al., 1993, *Mol. Cell. Endocrinol.* 90:R23-26; and Huper et al., 1992, *In Vitro Cell Dev. Biol.* 28A:730-734), and may be used to provide transcription of the inserted nucleotide sequence encoding the recombinant HIV chemokine.

Other regulatory elements for efficient gene transcription or message translation include enhancers, and regulatory signals. Enhancer sequences are DNA elements that appear to increase transcriptional efficiency in a manner relatively independent of their position and orientation with respect to a nearby gene. Thus, depending on the host cell expression vector system used, an enhancer may be placed either upstream

or downstream from the inserted nucleotide sequence encoding the recombinant HIV chemokine to increase transcriptional efficiency. One or more regulatory elements, such as transcription or translation
5 initiation signals, may be used to regulate the expression of the nucleotide sequence encoding the recombinant HIV chemokine. Such regulatory elements may be inserted into the nucleotide sequence encoding the recombinant HIV chemokine or nearby vector DNA sequences
10 using recombinant DNA methods described for insertion of DNA sequences.

Accordingly, a nucleotide sequence encoding for a recombinant HIV chemokine can be ligated into an expression vector at a specific site in relation to the
15 vector's promoter and regulatory elements so that when the recombinant vector is introduced into the host cell, the recombinant HIV chemokine is expressed from the recombinant vector in the host cell. For example, the nucleotide sequence containing its own regulatory
20 elements can be ligated into an expression vector in a relation or orientation to the vector promoter, and control elements which will allow for expression of the recombinant HIV chemokine. The recombinant vector is then introduced into the appropriate host cells, and the
25 host cells are selected, and screened for those cells containing the recombinant vector. Selection and screening may be accomplished by methods known in the art including detecting the expression of a marker gene (e.g., drug resistance marker or auxotrophic marker)
30 present in the vector; immunoscreening for production of recombinant HIV chemokine-specific epitopes using antisera generated to epitopes of HIV chemokine; probing the DNA of the host cells for a nucleotide sequence encoding a recombinant HIV chemokine using one or more
35 oligonucleotides, and methods known in the art; and a functional assay to test binding of the recombinant HIV

chemokine to a chemokine receptor which is known to bind to HIV chemokine.

EXAMPLE 7

5 This embodiment demonstrates the effects of introducing the gene sequence for the HIV chemokine(s) into a cell line. To illustrate this embodiment, a cell line stably producing multiple HIV-1 proteins but no infectious virus was used (HL2/3; Ciminale et al., 1990, AIDS
10 Research and Human Retroviruses, vol 6, p 1281-1286). HL2/3 was generated by stably transfecting HeLa cells with a hybrid HIV-1 clone HXB2/3gpt and selecting for stable production of HIV-1 proteins. Gag, Env, Tat, Rev, and Nef, but no reverse transcriptase, are produced
15 by this cell line and co-cultivation experiments demonstrate no viral propagation. It was intended as a fusion partner, along with another cell line expressing CD4 (HLCD4-CAT). No CD4 is expressed on the surface of the HL2/3 cell line as determined by flow cytometry.

20 HeLa cells (3.8×10^5 /well) were plated and then transfected the following day for 2 hours, followed by the addition of serum containing media and various treatments. A comparison of cells following either mock transfections (Transfectam, Promega) or transfections
25 with either pHIV-CAT (abbreviated pHIV; Nable et al., 1987, *Nature*, 326:711-713), or pwt Δ (Rizzuto et al., 1998, *Science*, 280:1949-53 and pHIV-CAT (abbreviated as pHIV+pwt) performed as described in Example 3, illustrates the effects of the HIV-1 LTR U3 and R
30 sequences (containing the HIV chemokine gene) on cell survival and morphology (Table 1 and Figure 10). Sequencing of the constructs indicated that plasmid pHIV-CAT contains the HIV-1 LTR U3 and R sequences 5' to the CAT gene, whereas the plasmid pwt Δ contains a
35 truncated gp-120 construct (Sodroski et al.) as well as

- 39 -

the HIV-1 LTR. HL2/3 cells, following transfection, were +/- stimulated with Ca ionophore (50ng/ml) and phorbol myristate acetate (50 ng/ml) or treated or not with affinity-purified rabbit antibody to HIV chemokine peptides (+Ab) and grown on coverslips for hematoxylin and eosin staining in 6-well plates. Four peptides were used together for generating the antibodies. These were peptide corresponding to amino acid 19-35 of SEQ ID NO:10, amino acid 51-71 of SEQ ID NO:2, amino acid 89-103 of SEQ ID NO:10 with a cysteine at N-terminal end, and amino acid 20-38 of SEQ ID NO:2. After 3 days, the coverslips were removed for staining and cell counts and viability were assessed by trypan blue exclusion. Cell morphology was assessed by phase contrast microscopy in the well and following staining (Figure 10).

TABLE 1

GROUP	TREATMENT	TOTAL CELLS x 10 ⁵ /ALIVE x 10 ⁵	% DEAD	COMMENTS
1	Mock, unstim.	4.6/ 4.5	1	normal HeLa
2	Mock, unstim; Ab	9.7/9.5	1	normal HeLa; increased
3	Mock, stim + Ab	7.1/6.9	1	normal cellular +/-clumps
4	pHIV, stim + Ab	5.1/2.8	45	pyknotic cells, giant cells
5	pHIV+pwt, stim+ Ab	3.6/1	72	++clumps, pyknotic, syncytium
6	Mock, stim	2.1/2.0	2	less cellular, few mitosis
7	pHIV, stim	1.3/1.1	15	less cellular, +/-pyknotic
8	pHIV+pwt, stim	1.2/0.9	25	+clumps, pyknotic

When representative coverslips from the above groups were stained and examined the following observations were made. Mock stimulated cells (Group 6; Figure 10A) were present in a monolayer with relatively uniform round to oval nuclei, low nuclear to cytoplasm ratio, abundant stellate amphophilic cytoplasm with cytoplasmic processes. Cellular nuclei contained finely granular, evenly distributed chromatin (1-3 prominent nucleoli). Scattered binucleated cells were also observed. For pHIVCAT transfected and stimulated cells

(Group 7; Figure 10B); viable cells with nuclear and cytoplasmic features similar to those in control (Figure 10A) were observed. However, there were numerous degenerated cells that contained pyknotic, shrunken
5 nuclei and eosinophilic cytoplasm (apoptotic). For pHIVCAT+pwt Δ transfected and stimulated cells (Group 8; Figure 10C), only a few cells were present. A single syncytium is shown in Figure 10C consisting of pyknotic nuclei and eosinophilic cytoplasm. Some nuclei with
10 partially clumped chromatin can also be seen.

For mock transfected, stimulated cells that received antibody to peptides 1-4 (Group 3; Figure 10D), cells were in a monolayer and similar to Group 6. However, the cytoplasm appeared more vacuolated, and
15 nucleoli were prominent and angulated. Figure 10D shows a single quadripolar mitotic figure. For cells transfected with pHIVCAT+pwt Δ , stimulated, and receiving antibody (Group 5; Figure 10E), syncytium was present but the nuclei were all shrunken and pyknotic.
20 The nuclear to cytoplasmic border was not discernable. Some of the uninucleate cells appeared to have somewhat shrunken nuclei containing condensed chromatin suggestive of degeneration. In an additional set of cells transfected with pHIVCAT+pwt Δ , stimulated and
25 receiving antibody, soluble CD4 was added (Figure 10F). Prominent syncytium with multiple nuclei containing prominent angulated nucleoli and vacuolated cytoplasm.

These data indicate that the addition of constructs that can generate antisense RNA encoding chemokine-like
30 proteins to a HeLa cell line that expressed the HIV proteins HIV-1 proteins, Gag, Env, Tat, Rev, and Nef, but no reverse transcriptase, resulted in cell degeneration and death. Additional expression of gp120 increased the effect indicating that gp120 may be acting
35 in association with the chemokine-like protein. These results further indicate that a chemokine-like protein

is produced from the antisense RNA transcribed off of the antisense initiator in HIV.

EXAMPLE 8

5 This embodiment illustrates that a recombinant HIV chemokine encoded by a nucleotide sequence according to the present invention can be purified from the host cell expression system using an affinity molecule such as by affinity chromatography. Also this embodiment
10 illustrates using an affinity molecule to purify HIV chemokine from cells infected with HIV. An affinity molecule is a molecule that has binding specificity to the recombinant HIV chemokine or HIV chemokine from infected cells. Such an affinity molecule may be
15 selected from the group consisting of a chemokine receptor (e.g., CCR5, CCR3, CCR2b, and CXCR4) or anti-HIV chemokine antisera (polyclonal or monoclonal, or anti-peptide HIV chemokine antisera). In one illustration, the recombinant HIV chemokine or HIV
20 chemokine may be purified from a culture of transfected or infected human cells. The cultured cells are lysed, cellular debris is removed by centrifugation, and the supernatant is then applied to an affinity column. The column is washed, and then the recombinant HIV chemokine
25 or HIV chemokine is eluted from the immobilized affinity molecule using methods known in the art. The purified recombinant CXC or HIV chemokine preparation may then be checked for purity by sodium dodecyl sulfate polyacrylamide gel electrophoresis; and for activity by
30 a binding assay. Alternatively, peptides derived from the HIV chemokine sequence can be linked to an affinity matrix (i.e. CNBr activated sepharose) and used to purify chemokine peptide-specific antibody for use in isolation and detection.

35

EXAMPLE 9

This embodiment illustrates that a monoclonal antibody (MAb) can be generated to epitopes specific for an HIV chemokine. Monoclonal antibodies to HIV chemokine may be developed using methods known in the art. For example, a method for making monoclonal antibodies immunoreactive with HIV chemokine involves the use of isolated and purified HIV chemokine as the immunogen; and an immunologically effective amount of the immunogen is used to immunize an animal (such as BALB/c mice) at timed intervals. A few days following the last immunization, spleens from the immunized animal are harvested aseptically, and placed into a tissue culture dish containing tissue culture medium. The primed spleen cells containing B-lymphocytes are mixed with a immunoglobulin non-secreting plasmacytoma cell line (usually a 10:1 to 1:1 ratio) for fusion. Fusion can be accomplished by methods including contacting the cells with a fusion agent such as polyethylene glycol (1 ml of a 50% solution, MW 1400) or by electrofusion. The cells from the fusion are then cloned out in microtiter plate wells. Typically, the plasmacytoma cell line is deficient in an enzyme such as hypoxanthine guanine phospho-ribosyl transferase such that fused hybridomas can be selected for by using a tissue culture selection medium such as a medium containing hypoxanthine, aminopterin, and thymidine. The hybridoma cultures are then incubated for several days, under standard tissue culture conditions, before the supernatants are tested for immunoreactivity to isolated and purified HIV chemokine. Alternatively, using methods standard in the art, human monoclonal antibodies may be made to an HIV chemokine (see. e.g., Ludwig et al, 1994, Cell. Imm.; Kanki and Takeuchi, 1995, *Hum. Antibodies Hybridomas*

6:89-92; Satoh et al., 1995, *Immunol. Lett.* 47:113-19;
Vollmers et al., 1995, *Cancer* 76:550-558).

Murine monoclonals can be modified (making them
more "human compatible") for administration into an
5 individual using techniques standard in the art (e.g.,
as reviewed by Adair, 1992, *Immunological Reviews* 130:
6-37, herein incorporated by reference). For example,
murine monoclonal antibodies may be "humanized" by
replacing portions of the murine monoclonal antibody
10 with the equivalent human sequence. In one embodiment,
a chimeric antibody is constructed. The construction of
chimeric antibodies is now a straightforward procedure
(Adair, 1992, *supra*, at p. 13) in which the chimeric
antibody is made by joining the murine variable region
15 to a human constant region. Additionally, chimeric
antibodies may be made by joining the hypervariable
regions of the murine monoclonal antibody to human
constant regions and parts of human variable regions
using one of several techniques known in the art.
20 Techniques for constructing chimeric antibodies (murine-
human) of therapeutic potential have been described
previously (see, e.g., Morrison et al., 1984, *Proc.*
Natl. Acad. Sci. 81:6851-6855; Larrick et al., 1991,
Hum. Antibod. Hybridomas 2:172-189; herein incorporated
25 by reference). Thus, in one embodiment of the present
invention, and using methods known in the art, the
murine variable region of the monoclonal antibody to HIV
chemokine according to the present invention is joined
to a human constant region to form a chimeric anti-HIV
30 chemokine monoclonal antibody having the same
specificity as the anti-HIV chemokine MAb. In general,
humanizing an murine MAb such as by making a chimeric
antibody limits the development of human anti-mouse
antibody responses. Additionally, the humanized
35 antibodies generally change the pharmacokinetics by

providing a longer half-life of such antibody, as compared to the half-life of murine antibody.

A chimeric MAb can also be constructed using a standard combination of techniques including polymerase chain reaction (PCR) cloning of antibody variable regions, the use of suitable expression vectors already containing the DNA encoding human constant region, insertion of the DNA for the murine MAb variable region into such vector in forming a recombinant vector, and expression of the resultant chimeric antibody by an expression system containing the recombinant vector (See, e.g., Daugherty et al., 1991, *Nucl. Acids Res.* 19:2471-2476; Maeda et al., 1991, *Human Antibodies and Hybridomas* 2:124-134; herein incorporated by reference).

One expression vector can be used in which the vector is constructed so that the variable region and constant region genes are in tandem. Expression systems known to those skilled in the art for production of antibody or antibody fragments include mammalian cells (e.g. cell lines such as COS, NSO, or CHO), phage expression libraries, *Escherichia coli*, and yeast (Adair, 1992, *supra*). Any one of these monoclonal antibodies (purified human antibodies or purified, chimeric monoclonal antibodies) may then be tested for their ability to interact with HIV chemokine in binding assays.

Anti-HIV chemokine antibodies may also be used in competitive drug screening assays to identify compounds that function to bind HIV chemokine thereby neutralizing one or more functional activities of HIV chemokine (e.g., chemotaxis, and/or chemokine receptor binding). For example, a drug compound is tested for its ability to compete with neutralizing antibodies (capable of binding HIV chemokine) for binding to HIV chemokine. Selection of such possible drug compounds may also be

facilitated by methods known in the art including determination of the three-dimensional structure of HIV chemokine (e.g., x-ray crystallography and/or computer modeling).

5

EXAMPLE 10

This Example illustrates the use of HIV chemokine or antibodies to HIV chemokine for use in diagnostic assays. HIV chemokine, isolated according to the method
10 of the present invention, or peptides formed therefrom, can be used as an antigen for diagnostic assays. Alternatively, HIV chemokine, or peptides formed therefrom, can be used as immunogens for generating anti-HIV chemokine antisera of diagnostic value.

15 Antigenic sites of a protein may vary in size but can consist of from about 7 to about 14 amino acids. Thus, a protein the size of HIV chemokine may contain several discrete antigenic epitopes. Using synthetic processes, peptides of at least 7 to 14 amino acids in size may be
20 generated which contain antigenic epitopes of HIV chemokine. The peptides can be synthesized from the amino acid sequence of an HIV chemokine using one of the several methods of peptide synthesis known in the art including standard solid peptide synthesis using
25 tertbutyl-oxycarbonyl amino acids (Mitchell et al., 1978, *J. Org. Chem.* 43:2845-2852); using 9-fluorenylmethyloxycarbonyl amino acids on a polyamide support (Dryland et al., 1986, *J. Chem. Soc. Perkin Trans. I*, 125-137); by pepscan synthesis (Geysen et al.,
30 1987, *J. Immunol. Methods* 03:259; 1984, *Proc. Natl. Acad. Sci. USA* 81:3998); or by standard liquid phase peptide synthesis. Modification of the peptides, such as by deletion and substitution of amino acids (and including extensions and additions to amino acids) and
35 in other ways, may be made so as to not substantially

detract from the immunological properties of the peptide. In particular, the amino acid sequence of the peptide may be altered by replacing one or more amino acids with functionally equivalent amino acids resulting in an alteration which is silent in terms of an observed differences in the binding specificity of the peptide.

In one embodiment, purified HIV chemokine, or peptides formed therefrom, may be used as antigens in immunoassays for the detection of antisera present in the body fluid of an individual. The body fluids include, but are not limited to, blood (e.g., serum) and urine. A diagnostic assay utilizing as an antigen HIV chemokine or a peptide formed therefrom, includes any immunoassay known in the art including, but not limited to, radioimmunoassay, ELISA, "sandwich" assay, precipitin reaction, agglutination assay, fluorescent immunoassay, and chemiluminescence-based immunoassay. Thus, for example, HIV chemokine or a peptide formed therefrom may be used as an antigen in an ELISA in which the antigen is immobilized to a selected surface; followed by blocking of unbound areas of the surface; contacting the body fluid sample with the selected surface containing immobilized antigen; washing the surface to remove materials in the sample which are not bound to the antigen; and detection of any immune complexes present (e.g., antibody to HIV chemokine complexed to the antigen) with a detectable moiety, such as by adding protein A peroxidase with subsequent color development. Other detectable moieties, conjugates and/or substrates known to those skilled in the art of diagnostics may be used to detect immunocomplexes formed. Thus, a diagnostic kit may contain the isolated HIV chemokine, or peptide formed therefrom as the antigen; a means for facilitating contact between the sample to be analyzed and the antigen (e.g., for an

ELISA, a microtiter plate or wells); and a means for detecting the presence of immunocomplexes formed.

In another embodiment of the invention, using antisera to epitopes of an HIV chemokine, the clinical sample is assayed for the presence of the antigen, i.e., HIV chemokine. This antisera may be used by contacting the clinical sample, and detecting the presence of immunocomplexes formed between the antisera and antigen that is present in the clinical sample. Thus, a diagnostic kit may contain the antibody generated to HIV chemokine epitopes; a means for facilitating contact between the clinical sample and the antibody; and a means for detecting the presence of immunocomplexes formed.

EXAMPLE 11

This embodiment of the present invention is to provide HIV chemokines, peptides formed therefrom, or modified variant of HIV chemokines (separately or collectively referred to as "HIV chemokine immunogen") to be used as immunogens in a prophylactic and/or therapeutic vaccine for active immunization to protect against or treat infections caused by HIV. For vaccine development, an HIV chemokine comprising the immunogen may be purified from HIV infected cells, or comprise recombinant HIV chemokine, using the methods according to the present invention. The HIV chemokine immunogen is included as the relevant immunogenic material in the vaccine formulation, and in immunoeffective amounts, to induce an immune response. Many methods are known for the introduction of a vaccine formulation into the human to be vaccinated. These include, but are not limited to, intradermal, intramuscular, intraperitoneal, intravenous, subcutaneous, ocular, intranasal, and oral administration. As known to those skilled in the art, the vaccine may further comprise a physiological carrier

such as a pharmaceutically acceptable solution, polymer or liposomes; and an adjuvant, or a combination thereof.

Various adjuvants are used in conjunction with vaccine formulations. The adjuvants aid in attaining a
5 more durable and higher level of immunity using smaller amounts of vaccine antigen or fewer doses than if the vaccine antigen were administered alone. The adjuvant may act to stimulate the immune effector cells, as well as delay release and degradation/processing of the HIV
10 chemokine immunogen to enhance immune recognition. Examples of adjuvants include incomplete Freund's adjuvant, Adjuvant 65 (containing peanut oil, mannide monooleate and aluminum monostearate), oil emulsions, glycolipid analogs, lipopeptides, Ribi adjuvant, the
15 pluronic polyols, polyamines, Avridine, Quil A, saponin, MPL, QS-21, and mineral gels such as aluminum hydroxide, aluminum phosphate, etc.

Another embodiment of this mode of the invention involves peptides derived from HIV chemokine as a
20 hapten, i.e. a molecule which cannot by itself elicit an immune response. In such case, the hapten may be covalently bound to a carrier or other immunogenic molecule which will confer immunogenicity to the coupled hapten when exposed to the immune system. Thus, such an
25 HIV chemokine-specific hapten linked to a carrier molecule may be the immunogen in a vaccine formulation. There are many such carriers known in the art including, but not limited to, keyhole limpet hemocyanin, bovine serum albumin, and diphtheria toxin cross-reactive
30 mutant protein ("CRM"). Additionally, there are several methods known in the art for conjugating a peptide to a carrier. Such methods include, but are not limited to, the use of glutaraldehyde, or succinimidyl *m*-maleimidobenzoate, or 1-ethyl-3-(3-dimethyl-aminopropyl)carbodiimide, or the use of bromo-acetylated
35

- 50 -

peptide (see, e.g. Robey et al., 1989, *Anal. Biochem.* 177:373-377).

In another embodiment, as an alternative to active immunization, such as where an individual is suffering from late stages of AIDS, immunization may be passive, i.e. immunization comprising administration of a therapeutically effective amount of purified human-compatible anti-HIV chemokine antibodies (e.g., chimeric or human compatible monoclonal antibodies).

EXAMPLE 12

This Example illustrates methods of administration of HIV chemokine, peptides formed therefrom, or modified variant of HIV chemokine, as agonists or antagonists (separately or collectively referred to as "HIV chemokine therapeutic"). The HIV chemokine therapeutic may be formulated in a pharmaceutically acceptable, nontoxic, carrier. Pharmaceutically acceptable carriers are generally known to include aqueous solutions such as water, various phosphate buffers, various buffered salines, alcoholic/aqueous solutions, and emulsions or suspensions; wherein the ionic strength, pH, and other properties of the pharmaceutically acceptable carrier may be adjusted to maximize delivery and activity of the HIV chemokine therapeutic to that site. Regarding pH, generally a pH range of 6 to 8 is typically used. It will be appreciated by those skilled in the art that the carrier may comprise any suitable pharmaceutically acceptable liposome having incorporated therein an HIV chemokine therapeutic according to the present invention. Such liposomal compositions may be administered in any conventional mode for therapeutic treatment. The pharmaceutically acceptable carrier may additionally comprise an agent that may improve the solubility of the HIV chemokine therapeutic while not inhibiting the binding activity of the HIV chemokine

- 51 -

therapeutic. Such an additional agent may include, but is not limited to, a low concentration (e.g. concentration of 0.1% or less) of a nonionic detergent.

Depending on the physiologic site to be treated,
5 the health of the individual to be treated, and the nature of the formulation, the HIV chemokine therapeutic may be administered in any one of the standard methods known in the art for administration of therapeutic agents, including, but not limited to, topical, by
10 injection (e.g., intravenously), aerosol spray, intranasal, transmucosal, transdermal, and orally (by administered pills or liquids). As appreciated by those skilled in the art, dosage and frequency of dosage of an HIV chemokine therapeutic will depend on multiple
15 patient variables, including the severity of AIDS, age, weight, responsiveness to therapy, tolerance of therapeutic, and clearance rate of therapeutic.

Having described the preferred embodiments of the
20 present invention, it will be apparent to one of ordinary skill in the art that various modifications may be made to the disclosed embodiments, and that such modifications are intended to be within the scope of the present invention.

What is claimed is:

1. A nucleic acid encoding a HIV-chemokine selected from the group consisting of:
 - 5 a. an antisense RNA;
 - b. a DNA sequence located on the plus strand of HIV pro virus which allows antisense initiation to produce the antisense RNA of a.
 - c. double stranded DNA which allows antisense
 - 10 initiation to produce the antisense RNA of a.
2. The antisense RNA of claim 1, wherein the sequence of the RNA is selected from the group consisting of SEQ ID NO:6, SEQ ID NO:21, Seq ID NO:25, SEQ ID NO:26, or a
15 sequence having at least a 90% homology to SEQ ID NO:6, SEQ ID NO:21, SEQ ID NO:25 or SEQ ID NO:26.
3. The antisense RNA of claim 1 wherein the HIV chemokine encoded by the antisense RNA is selected from
20 the group consisting of SEQ ID NO.2, SEQ ID NO.7, SEQ ID NO.8, SEQ ID NO.9, SEQ ID NO.10, SEQ ID NO.11, SEQ ID NO.12, SEQ ID NO.13, SEQ ID NO.14, SEQ ID NO.15, SEQ ID NO.16, SEQ ID NO.17, SEQ ID NO.18, SEQ ID NO.19, SEQ ID NO.20, SEQ ID NO.22, SEQ ID NO.23, and SEQ ID NO.24.
25
4. A HIV chemokine selected from the group consisting of SEQ ID NO.2, SEQ ID NO.7, SEQ ID NO.8, SEQ ID NO.9, SEQ ID NO.10, SEQ ID NO.11, SEQ ID NO.12, SEQ ID NO.13, SEQ ID NO.14, SEQ ID NO.15, SEQ ID NO.16, SEQ ID NO.17,
30 SEQ ID NO.18, SEQ ID NO.19, SEQ ID NO.20, SEQ ID NO.22, SEQ ID NO.23, and SEQ ID NO.24.

Published <i>With international search report.</i> <i>Before the expiration of the time limit for amending the claims</i> <i>and to be republished in the event of the receipt of amendments.</i> (88) Date of publication of the international search report: 23 September 1999 (23.09.99)
(54) Title: HIV CHEMOKINES (57) Abstract Disclosed is a novel gene comprising an open reading frame encoded on the plus strand of the pro-viral DNA, and located in the region of HIV-1 long terminal repeat. The gene encodes a protein that is related to, and has a structural motif resembling that of chemokine proteins. Depending upon the ribosomal frameshift, a plurality of proteins may be translated from the antisense RNA. The protein has similarity with chemokine SDF-1 and may play a role as a cofactor with gp120 in the binding to and entry of HIV to a target cell.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US99/03162

A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) :A61K 39/21; C07H 21/02, 21/04

US CL :424/208.1; 536/23.1, 23.72

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 424/208.1; 536/23.1, 23.72

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

APS, GenCore

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	CHOE, H. et al. The B-Chemokine Receptors CCR3 and CCR5 Facilitate Infection by Primary HIV-1 Isolates. Cell. 28 June 1996, Vol. 85, pages 1136-1148, please see entire document.	1-4
A	ENDRES, M.J. et al. CD4-Independent Infection by HIV-2 Is Mediated by Fusin/CXCR4. Cell. 15 November 1996, Vol. 87, pages 745-756, please see entire document.	1-4

☐ Further documents are listed in the continuation of Box C. ☐ See patent family annex.

* Special categories of cited documents:	*T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
A document defining the general state of the art which is not considered to be of particular relevance	*X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
E earlier document published on or after the international filing date	*Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
L document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	*A* document member of the same patent family
O document referring to an oral disclosure, use, exhibition or other means	
P document published prior to the international filing date but later than the priority date claimed	

Date of the actual completion of the international search
